Abstract—Cognitive radio technology is an innovative radio design concept which aims to increase spectrum utilization by exploiting unused spectrum in dynamically changing environments. By extending previous results, we investigate the capacity gains achievable with this dynamic spectrum approach in asymmetric fading channels. More specifically, we allow the secondary-to-primary and secondary-to-secondary user channels to undergo Rayleigh or Rician fading, with arbitrary link power. In order to compute the capacity, we derive the distributions of ratios of Rayleigh and Rician variables. Compared to the symmetric fading scenario, our results indicate several interesting features of the capacity behaviour under both average and peak received power constraints. Finally, the impact of multiple primary users on the capacity under asymmetric fading has also been studied.

I. INTRODUCTION

Conservative spectrum policies employed by regulatory authorities have resulted in spectrum underutilization of the overall available spectrum for wireless communications. Measurements performed by agencies such as the Federal Communications Commission [1] in the United States and Ofcom [2] in the United Kingdom have revealed that at any given time, large portions of spectrum are sparsely occupied. Findings of such campaigns on spectrum usage have challenged the traditional spectrum management approaches.

The concept of cognitive radio (CR) [3] refers to a smart radio which can sense the external electromagnetic environment and adapt its transmission parameters according to the current state of the environment. CRs can access parts of the spectrum for their information transmission, provided that they cause minimal interference to the primary users in that band [5], [6]. Therefore, spectrum sharing among the primary licensee and the secondary CR must be carried out in a controlled fashion. In the technical literature, the *interference temperature* introduced by Kolodzy [7], [4] indicates the interference level at the primary licensee's receiver. From the licensees' point of view, the secondary access can be controlled in two ways. The total interference power can be required to remain below a certain threshold (an interference temperature constraint) or the signal-to-noise-and-interference (SINR) can be constrained.

The capacity of wireless systems has been extensively studied under fixed spectrum access. For CR, this work is less mature and many information/communication theoretic problems and implementation issues [8] remain to be solved. However,

several interesting results on the capacity, outage probability and throughput of CR systems have recently emerged. See for example, [10], [11], [9]. In [9], Gastpar derived the capacity of different non-fading additive-white-Gaussian-noise (AWGN) channels with the average received-power at a primary receiver being constrained. In [10], Ghasemi and Sousa showed that with the same limit on the received-power level, channel capacity for a range of fading models (e.g., Rayleigh, Nakagami- m and log-normal fading) exceeds that of the non-fading AWGN channel. In some scenarios, primary user spectral activity in the vicinity of the cognitive transmitter may differ from that in the vicinity of the cognitive receiver. Considering this, in [11], the capacity of opportunistic spectrum acquisition in the presence of distributed spectral activity has been investigated.

We extend the work in [10] which assumed that fading conditions for the interference path (CR transmitter-primary receiver) and the desired path (CR transmitter-CR receiver) are the same. In practice, these two links could experience different fading conditions (types) and different link powers (due to path length or shadowing). This is referred as *asymmetric* fading in this paper.

In this paper we consider Rayleigh and Rician fading. Hence, we are able to quantify the effects of propagation paths consisting of both line-of-sight (LoS) and scattered components. Building on the work in [10], this paper makes the following main contributions:

- 1) The secondary capacity under average-received power and peak-power constraints is studied for asymmetric conditions including different fading types (Rayleigh and Rician) and different link powers. Here we show that under low interference to the primary receiver, the secondary capacity is sensitive to the fading type on the desired and interference paths.
- 2) The impact of multiple primary licensee receivers in Rayleigh and Rician fading is studied for peak power constraints.
- 3) Closed-form expressions for the cumulative distribution function (CDF) and the probability density function (PDF) of a random variable (RV), g_1/g_0 is derived, for the cases where $(\sqrt{g_1}, \sqrt{g_0})$ experience (Rayleigh, Rician) and (Rician, Rayleigh) fading. This is needed to derive the above mentioned capacities.

Fig. 1. Shared spectrum usage between primary and secondary users.

This paper is organized as follows. The system and channel model is described in Section II. In Section III we derive the exact PDFs for the ratio of Rayleigh and Rician RVs. In Section IV, these results are used to study the capacity gains under average/peak received-power constraints respectively. Extensions of these results to multiple primary users are presented in Section V. Finally, some conclusions are drawn in Section VI. Throughout the paper, the reference to average/peak received-power refers to as the average/peak interference power at the primary receiver. The CR link is also referred to as a secondary link.

II. SYSTEM AND CHANNEL MODEL

In this section, the system and channel model considered in the paper are briefly outlined (cf. Fig. 1). The system model is borrowed from [10], however we have considered asymmetric fading scenarios. A point-to-point flat fading channel with perfect channel side information available to both the receiver and the transmitter is assumed. Let g_0 and g_1 denote the instantaneous channel gains from the secondary transmitter to the primary and secondary receivers respectively. Furthermore, we denote the respective PDFs by $p_{g_0}(g_0)$ and $p_{g_1}(g_1)$. For a unit power channel gain, the Rayleigh PDF is given by

$$p_{\sqrt{g}}(x) = 2xe^{-x^2} \quad (1)$$

for $x \geq 0$. For a Rician distribution the PDF is given by

$$p_{\sqrt{g}}(x) = 2x(1+K)e^{-K-(1+K)x^2}I_0\left(2x\sqrt{K+K^2}\right) \quad (2)$$

for $x \geq 0$, where K is the Rician K -factor defined as the ratio of signal power in dominant component over the scattered power and $I_0(\cdot)$ is the zeroth-order modified Bessel function of the first kind. For $K = 0$, Rayleigh fading is experienced and $K = \infty$ gives the AWGN (no fading) situation. Values of the K -factor in indoor/outdoor land mobile applications normally range from 0–12 dB [12]. In a practical environment the CR transmitter to CR receiver link may not be of the same length as the CR interference path to the primary receiver. When the link powers, $E\{g_0\}$ and $E\{g_1\}$, differ, it can be shown that capacity only depends on the power ratio. Hence, we define the relative power parameter, c , by $c = E\{g_1\}/E\{g_0\}$. Note that $E\{\cdot\}$ denotes the expectation operator.

Two important items of notation should be stressed at this point. Since the main results of the paper depend on the ratio g_1/g_0 , we use the shorthand notation Rayleigh/Rician to indicate that $\sqrt{g_1}$ is Rayleigh and $\sqrt{g_0}$ is Rician. Similarly, Rician/Rayleigh indicates that $\sqrt{g_1}$ is Rician and $\sqrt{g_0}$ is Rayleigh. The second issue is that the secondary transmitter must constrain its power so that the interference at the primary is acceptable. Hence the power constraints in this scenario are really interference constraints. This is different to many other problems where the constraints are for transmit power.

III. CDF AND PDF OF g_1/g_0

Here, we anticipate the results of Section IV, where it is shown that capacity depends on the ratio, g_1/g_0 . Hence, in this section the CDF and the PDF for a Rayleigh/Rician RV and a Rician/Rayleigh RV are derived.

Consider the distribution of a Rayleigh/Rician RV, $X = g_1/g_0$. Mathematically, $P(X < x)$, i.e., the CDF of X , is given by

$$P(X < x) = \int_0^\infty P\left(\frac{g_1}{g_0} < x | g_0\right) p_{g_0}(g_0) dg_0 \quad (3)$$

Equation (3) can be simplified as

$$P(X < x) = (K+1)e^{-K} \int_0^\infty (1 - e^{-xg_0}) \cdot e^{-(K+1)g_0} I_0(2\sqrt{K(K+1)g_0}) dg_0 \quad (4)$$

The integral in (4) can be solved using [13, eq. 2.15.5.4] and we obtain the CDF of X as

$$F_X(x) = 1 - \frac{K+1}{x+K+1} e^{-K+\frac{K^2+K}{x+K+1}} \quad (5)$$

for $x \geq 0$. The PDF of X can be found by taking the derivative of (5) with respect to x , yielding

$$p_X(x) = (K+1) \frac{x+(K+1)^2}{(x+K+1)^3} e^{-K+\frac{K^2+K}{x+K+1}} \quad (6)$$

for $x \geq 0$. As expected, for $K = 0$ the PDF $p_X(x)$ is given by $p_X(x) = 1/(x+1)^2$ [10, eq. 11].

Now consider the distribution of $Y = g_1/g_0$ when $\sqrt{g_1}$ is Rician and $\sqrt{g_0}$ is Rayleigh. Using the same approach, $P(Y < y)$ is given by

$$P(Y < y) = 1 - \int_0^\infty Q_1\left(\sqrt{2K}, \sqrt{2(1+K)y}g_0\right) e^{-g_0} dg_0 \quad (7)$$

where $Q_1(a, b) = \int_b^\infty xe^{-\frac{a^2+b^2}{2}} I_0(ax) dx$ is the first-order Marcum Q -function which satisfies the following identity [14, eq. 5]

$$Q_1(a, b) + Q_1(b, a) = 1 + e^{-\frac{a^2+b^2}{2}} I_0(ab) \quad (8)$$

Using (8), we can express (7) as shown in (9). The first integral in (9) can be evaluated in closed-form using the result of [13, eq. 2.15.5.4] and is

$$I_1 = \frac{e^{-K+\frac{Ky+K^2y}{y+K+1}}}{y+K+1} \quad (10)$$

$$P(Y < y) = - \int_0^\infty e^{-(y+Ky+1)g_0} I_0(2\sqrt{(Ky+K^2y)g_0}) dg_0 + \int_0^\infty Q_1(\sqrt{2(y+Ky)g_0}, \sqrt{2K}) e^{-g_0} dg_0 \quad (9)$$

The second integral in (9) can be evaluated using the result of [15, eq. 25] as $I_2 = e^{-\frac{K}{y+Ky+1}}$. Hence, $P(Y < y)$ is given by

$$F_Y(y) = e^{-\frac{K}{y+Ky+1}} - \frac{e^{-K+\frac{Ky+K^2y}{y+Ky+1}}}{y+Ky+1} \quad (11)$$

for $y \geq 0$. After taking the derivative of (11) with respect to y , we obtain the PDF of Y as

$$p_Y(y) = \frac{K(1+K)}{(y+Ky+1)^2} e^{-\frac{K}{y+Ky+1}} + \frac{(1+K)^2(1-K+y)}{(y+Ky+1)^3} e^{-K+\frac{Ky+K^2y}{y+Ky+1}} \quad (12)$$

for $y \geq 0$. For Rayleigh/Rayleigh fading, the PDF $p_Y(y)$ simplifies to $p_Y(y) = 1/(y+1)^2$ [10, eq. 11]. To confirm the derivations, the PDFs of (6) and (12) were validated by Monte Carlo simulations, and a perfect match was obtained.

IV. CAPACITY GAINS OF SPECTRUM SHARING

A. Capacity Under an Average Received-Power Constraint

In this section, we investigate the capacity gains achievable by the secondary user under an average received-power constraint. In [10], the channel capacity was expressed as

$$C = \int \int B \log_2 \left(1 + \frac{g_1 P(g_0, g_1)}{N_0 B} \right) p_{g_0}(g_0) p_{g_1}(g_1) dg_0 dg_1 \quad (13)$$

such that

$$\int_0^\infty \int_0^\infty g_0 P(g_0, g_1) p_{g_0}(g_0) p_{g_1}(g_1) dg_0 dg_1 \leq Q \quad (14)$$

where Q is the maximum average interference power tolerated by the primary receiver², B is the available bandwidth, N_0 is the noise power at the secondary receiver and $P(g_0, g_1)$ denotes the optimal power allocation. Using the Lagrangian technique, [10] has found $P(g_0, g_1)$ to be

$$P(g_0, g_1) = \left(\frac{1}{\lambda_0 g_0} - \frac{N_0 B}{g_1} \right)^+ \quad (15)$$

where $(\cdot)^+$ denotes $\max\{\cdot, 0\}$. Note that λ_0 is determined such that the average receive power is equal to Q . That is mathematically

$$\int_{g_0} \int_{g_1} \left(\frac{1}{\lambda_0} - N_0 B \frac{g_0}{g_1} \right)^+ p_{g_1}(g_1) p_{g_0}(g_0) dg_1 dg_0 = Q \quad (16)$$

Hence, the channel capacity can be calculated from

$$C = B \int_{\frac{1}{\gamma_0}}^\infty \log_2(\gamma_0 g_{10}) p_{\frac{g_1}{g_0}}(g_{10}) dg_{10} \quad (17)$$

²The quality of transmission at the primary receiver can also be measured using the SINR. This requires a knowledge of the primary transmitter to primary receiver channel.

where $\gamma_0 = 1/(\lambda_0 N_0 B)$ and $p_{\frac{g_1}{g_0}}(\cdot)$ denotes the PDF of g_1/g_0 . To the best of the authors' knowledge, there are no closed-form solutions for the integral in (16) for the two fading scenarios considered in this paper. Rewriting (16) gives

$$\int_0^{\gamma_0} (\gamma_0 - x) p(x) dx = \frac{Q}{N_0 B} = \alpha \quad (18)$$

where $p(x)$ in (18) denotes the PDF of g_0/g_1 . Therefore, α is the allowable interference-to-noise power ratio at the primary receiver. Using integration by parts, (18) can be further simplified as

$$\int_0^{\gamma_0} F(x) dx = \alpha \quad (19)$$

where $F(x)$ denotes the CDF of g_0/g_1 . Hence, using (19) we have calculated γ_0 numerically. Note that the calculations in (13)-(19) are general and apply to both the equal power ($c = 1$) and the unequal power ($c \neq 1$) case. In Section III the required PDFs and CDFs were derived for the equal power case. When $c \neq 1$, it is a simple process to repeat the steps in (13)-(19) and to show that using $c\alpha$ instead of α in (19) with the equal power results from Section III gives the correct results. Hence, we only require the PDF and CDF of $g_1/g_0, g_0/g_1$ for the equal power case. To obtain results for the unequal power case, we simply use $c\alpha$ rather than α in (19). This is equivalent to replacing N_0 by N_0/c , which makes intuitive sense since a power ratio of c implies that the secondary receiver receives a signal c times stronger than the primary. Hence, relative to the equal power case the SNR is c times bigger and the equivalent noise level is N_0/c .

Figs. 2 and 3 show the secondary capacity versus α and under an average received interference power constraint. In all plots, AWGN refers to the scenario where g_0 and g_1 are equal to unity all the time [10]. We make the following noteworthy observations:

- 1) The secondary capacity increases if the primary receiver can tolerate more interference. This is because the secondary transmitter is able to transmit with higher power (probabilistically).
- 2) The case of interest in engineering practice is for a low value of α , i.e., when the acceptable CR interference is correspondingly low. Here we see that the capacity can be sensitive to the type of fading and indeed the symmetric fading, i.e., the Rayleigh/Rayleigh case significantly overestimates the capacity compared to the Rayleigh/Rician case in the low α regime. This observation is central to our contribution in this paper. The difference in capacity reduces to almost zero when the acceptable interference at the primary is large.
- 3) The capacity of Rician/Rayleigh fading (cf. Fig. 3) is not so sensitive to the K -factor (0 – 15) dB. For a given

Fig. 2. Capacity under an average received-power constraint against α in Rayleigh/Rician fading. $c = 0$ dB.

Fig. 3. Capacity under an average received-power constraint against α in Rician/Rayleigh fading. $c = 0$ dB.

Fig. 4. Capacity under a peak received-power constraint against α in Rayleigh/Rician fading. $c = 0$ dB.

Fig. 5. Capacity under a peak received-power constraint against α in Rician/Rayleigh fading. $c = 0$ dB.

α , the Rayleigh fading on the primary link determines the transmit power of the secondary user. Once this is determined, the resulting secondary user capacity is less sensitive to the K -factor within the considered range of 0 – 15 dB. This is in contrast with Rayleigh/Rician fading, (cf. Fig. 4), where we see that the K -factor induces an appreciable capacity difference especially in the low α regime. As K -factor decreases and in the low α regime, more opportunities for the secondary user to transmit with relatively high power are created. However, for large α , the impact of changing K -factor on the secondary user transmit power is reduced.

- 4) Under fading, the secondary capacity is higher than the AWGN case. This observation is consistent with the findings of [10]. In a fading environment, the secondary user can transmit with high power, when its signal received by the primary user is subject to deep fades.

B. Capacity Under a Peak Received-Power Constraint

As discussed in [10], although *average* received-power is reasonable for delay insensitive applications, in other cases it is desirable to impose a peak received-power constraint. Under the peak received-power constraint [10]

$$g_0 P(g_0, g_1) \leq Q \quad (20)$$

and the channel capacity was given in [10] as

$$C = B \int_0^\infty \log_2(1 + \alpha x) p_{\frac{g_1}{g_0}}(x) dx \quad (21)$$

Therefore, under Rayleigh/Rician fading the channel capacity is obtained by substituting the PDF in (6) into (21). This gives

$$C = (K + 1)B \int_0^\infty \log_2(1 + \alpha x) \frac{x + (K + 1)^2}{(x + K + 1)^3} \times e^{-K + \frac{K^2 + K}{x + K + 1}} dx \quad (22)$$

$$C = K(1+K)B \int_0^\infty \log_2(1+\alpha x) \frac{e^{-\frac{K}{x+Kx+1}}}{(x+Kx+1)^2} dx + (1+K)^2 B \int_0^\infty \log_2(1+\alpha x) \frac{(1-K+x)}{(x+Kx+1)^3} e^{-K+\frac{Kx+K^2x}{x+Kx+1}} dx \quad (23)$$

Fig. 6. Capacity under average and peak received-power constraints against α in Rician/Rayleigh and Rayleigh/Rician fading for two different values of c . $K = 6$ dB.

Similarly, under Rician/Rayleigh fading the channel capacity is given by (23) on the next page. The case where the shadowing on the two links is different can be derived using the same arguments as above. Hence, numerical results are obtained assuming g_1 and g_0 have equal power but α is replaced by $c\alpha$.

Figs. 4 and 5 show the secondary capacity versus α and under a peak received interference power constraint. We make the following noteworthy observations:

- 1) Like the average interference power case, the capacities increase if the primary can tolerate more interference.
- 2) The secondary capacity is sensitive to the type of fading on the two links and depending on the fading type on either link one could overestimate the capacity especially for low values of α and Rayleigh/Rician fading.
- 3) From [10, Fig. 4] in symmetric fading conditions, the capacity under a peak received power constraint is always higher than the AWGN case. However in Rayleigh/Rician fading, we see that the capacity is higher/lower than the AWGN case depending on the α .

Fig. 6 shows the impact of signal power differences on CR capacity. Such differences usually arise from shadowing and path length differences. We assume two values for the power ratio between the links, $c = 10$ dB and $c = -10$ dB. The effect on CR capacity is a simple scaling by the c parameter. Hence, we have a simple and efficient approach to investigating such asymmetric links.

V. EFFECT OF MULTIPLE PRIMARY USERS

When $n > 1$ primary users are present, the transmit/receive powers of the secondary user would be subject to additional

Fig. 7. Capacity under a peak received-power constraint and Rician/Rayleigh fading for different numbers of primary receivers. $K = 6$ dB.

Fig. 8. Capacity under a peak received-power constraint and Rayleigh/Rician fading for different numbers of primary receivers. $K = 6$ dB.

constraints. This leads to a capacity reduction [10]. Let g_{0i} denote the channel gain of the secondary transmitter to the i -th primary receiver. In this case, the peak received-power constraint is reformulated by the following constraint

$$P(g_{01}, g_{02}, \dots, g_{0n}, g_1) \leq \min_i \frac{Q}{g_{0i}}, \quad i = 1, \dots, n \quad (24)$$

The channel capacity is given by

$$C = B \int_0^\infty \log_2(1+\alpha z) p_Z(z) dz \quad (25)$$

where $Z = g_1 / \max_i g_{0i}$. In Appendix A we have derived the PDF for Z when $\sqrt{g_{0i}}$, $i = 1, \dots, n$ are independent and

$$C = nB \sum_{k=0}^{n-1} (-1)^k \binom{n-1}{k} \int_0^\infty \log_2(1 + \alpha x) \frac{1}{(1+k+(1+K)x)^2} e^{-\frac{(1+k)K}{1+k+(1+K)x}} \left(1 + K + \frac{K(K+1)^2 x}{1+k+(K+1)x}\right) dx \quad (26)$$

identically distributed (i.i.d) Rayleigh RVs and $\sqrt{g_1}$ is a Rician RV. Substituting this PDF into (25) results in the capacity given by (26). Such a result can be extended to the unequal power case by considering the maximum of independent Rayleigh variables with differing means. This is possible using standard order statistic results, but is beyond the scope of the paper.

Unfortunately, the PDF for the case when $\sqrt{g_{0i}}$, $i = 1, \dots, n$ are i.i.d Rician RVs and $\sqrt{g_1}$ is a Rayleigh RV could not be found in closed-form. Instead we have resorted to *time consuming* Monte-Carlo simulations to obtain the capacity. The average received-power case appears to be rather complex and is not considered here. Figs. 7 and 8 illustrate the CR capacity for $n = 1, 2, 3$ and Rayleigh/Rician and Rician/Rayleigh fading respectively. In all cases, the capacity reduces compared to the AWGN case as n gets larger.

VI. CONCLUSIONS

In this paper we have investigated the impact of asymmetric fading on the secondary user capacity under average and peak interference power constraints. Compared to symmetric fading conditions assumed in the previous literature, our analysis have added several new insights, especially for a low value of α , i.e., the regime that most CRs would expect to operate in practice. The results show that under Rayleigh/Rician fading and low α , the capacity is significantly lower than that in a symmetric Rayleigh/Rayleigh fading scenario, and as α increases, the impact of K -factor on the capacity is reduced. Under Rician/Rayleigh fading, the capacity results change only slightly with different K -factors within considered range of 0 – 15 dB. The capacity results were also extended to include the effects of different power gain and multiple primary users.

APPENDIX A

DERIVATIONS WITH MULTIPLE PRIMARY USERS

Let $\sqrt{g_{0i}}$, for $i = 1, \dots, n$, be i.i.d Rayleigh RVs and let $\sqrt{g_1}$, which is independent of all g_{0i} , have a Rician distribution. Define $g_0 = \max_i g_{0i}$ for $i = 1, \dots, n$ and $U = g_1/g_0$. Then the CDF of U is given by

$$P(U < u) = \int_0^\infty P(g_1 < g_0 u | g_0) p_{g_0}(g_0) dg_0 \quad (27)$$

The PDF of g_0 , $p_{g_0}(g_0)$ is given by [16, eq. 9.326] as

$$p_{g_0}(g_0) = n \sum_{k=0}^{n-1} (-1)^k \binom{n-1}{k} e^{-(1+k)g_0} \quad (28)$$

Substituting (28) into (27) we obtain

$$P(U < u) = 1 - n \sum_{k=0}^{n-1} (-1)^k \binom{n-1}{k} \times \int_0^\infty Q_1\left(\sqrt{2K}, \sqrt{2(1+K)ut}\right) e^{-(1+k)t} dt \quad (29)$$

After solving the integral in (29), we express $P(U < u)$ in closed-form as

$$F_U(u) = 1 - n \sum_{k=0}^{n-1} \frac{(-1)^k}{1+k} \binom{n-1}{k} \times \left(1 - \frac{(1+K)u}{1+k+(1+K)u} e^{-\frac{(1+k)K}{1+k+(1+K)u}}\right) \quad (30)$$

Finally, differentiation of $P(U < u)$ with respect to u , yields the PDF of U . Therefore, the PDF of U is given by

$$p_U(u) = n \sum_{k=0}^{n-1} (-1)^k \binom{n-1}{k} \frac{1}{(1+k+(1+K)u)^2} \times e^{-\frac{(1+k)K}{1+k+(1+K)u}} \left(1 + K + \frac{K(K+1)^2 u}{1+k+(K+1)u}\right) \quad (31)$$
